

Podání tekutin je doporučeno jen v případě, že možnou příčinou oběhové zástavy je hypovolemie.

Závěr

Evidence o farmakologii během oběhové zástavy zůstává i nadále zcela nedostatečná. U některých léků se jejich slibné účinky projevily pouze na zvířecích modelech a nebyly potvrzené ve velkých klinických studiích.

Řada z testovaných léků zvýšila šanci na dosažení ROSC nebo zlepšila krátkodobé přežití, ale neovlivnila dlouhodobé přežívání či neurologický výsledek. Nezpochybnitelné důkazy nemáme ani pro základ současné farmakoterapie u srdeční zástavy – adrenalin. Je proto třeba další intenzivní výzkumné práce k nalezení optimální a důkazy podložené farmakologické léčby u srdeční zástavy.
